Non-trivial applications require functional and load testing beyond "shift-F5" and a developer checking his own work manually. This is particularly true for richer interfaces, like those that can be created with Flex. RIAs allow for richer user interaction and more permutations that require testing. This session will introduce you to functional and load testing techniques, methodologies, and software related to testing Flex applications. While the performance testing information can be applied to any backend server product, specific attention will be paid to the use of ColdFusion as the backend server. Some previous experience with Flex will be helpful, but not essential, for this session.
